## talagrand's convex distance

The weighted Hamming distance is

$$
\boldsymbol{d}_{\alpha}(x, A)=\inf _{y \in A} \boldsymbol{d}_{\alpha}(x, y)=\inf _{y \in A} \sum_{i: x_{i} \neq y_{i}}\left|\alpha_{i}\right|
$$

where $\alpha=\left(\alpha_{1}, \ldots, \alpha_{\boldsymbol{n}}\right)$. The same argument as before gives

$$
\mathbb{P}\left\{\boldsymbol{d}_{\alpha}(\boldsymbol{X}, \boldsymbol{A}) \geq \boldsymbol{t}+\sqrt{\frac{\|\alpha\|^{2}}{2} \log \frac{1}{\mathbb{P}\{\boldsymbol{A}\}}}\right\} \leq \boldsymbol{e}^{-2 \boldsymbol{t}^{2} /\|\alpha\|^{2}},
$$

This implies

$$
\sup _{\alpha:\|\alpha\|=1} \min \left(\mathbb{P}\{\boldsymbol{A}\}, \mathbb{P}\left\{\boldsymbol{d}_{\alpha}(\boldsymbol{X}, \boldsymbol{A}) \geq \boldsymbol{t}\right\}\right) \leq e^{-t^{2} / 2}
$$

## convex distance inequality

convex distance:

$$
\boldsymbol{d}_{\boldsymbol{T}}(x, \boldsymbol{A})=\sup _{\alpha \in[0, \infty)^{n}:\|\alpha\|=1} d_{\alpha}(x, \boldsymbol{A})
$$

Talagrand's convex distance inequality:

$$
\mathbb{P}\{A\} \mathbb{P}\left\{d_{T}(X, A) \geq t\right\} \leq e^{-t^{2} / 4}
$$

Follows from the fact that $\boldsymbol{d}_{\boldsymbol{T}}(\boldsymbol{X}, \boldsymbol{A})^{2}$ is $(4,0)$ weakly self bounding (by a saddle point representation of $\boldsymbol{d}_{\boldsymbol{T}}$ ).

Talagrand's original proof was different.

## convex lipschitz functions

For $\boldsymbol{A} \subset[0,1]^{n}$ and $x \in[0,1]^{n}$, define

$$
D(x, A)=\inf _{y \in A}\|x-y\| .
$$

If $\boldsymbol{A}$ is convex, then

$$
D(x, A) \leq d_{T}(x, A) .
$$

Proof:

$$
D(x, \boldsymbol{A})=\inf _{\nu \in \mathcal{M}(\boldsymbol{A})}\left\|x-\mathbb{E}_{\nu} \boldsymbol{Y}\right\| \quad \text { (since } \boldsymbol{A} \text { is convex) }
$$

$$
\leq \inf _{\nu \in \mathcal{M}(A)} \sqrt{\sum_{j=1}^{n}\left(\mathbb{E}_{\nu} \mathbb{1}_{x_{j} \neq Y_{j}}\right)^{2}} \quad\left(\text { since } x_{j}, Y_{j} \in[0,1]\right)
$$

$$
\begin{aligned}
& =\inf _{\nu \in \mathcal{M}(\boldsymbol{A})} \sup _{\alpha:\|\alpha\| \leq 1} \sum_{j=1}^{n} \alpha_{j} \mathbb{E}_{\nu} \mathbb{1}_{x_{j} \neq Y_{j}} \quad \text { (by Cauchy-Schwarz) } \\
& =\boldsymbol{d}_{\boldsymbol{T}}(\boldsymbol{x}, \boldsymbol{A}) \quad \text { (by minimax theorem). }
\end{aligned}
$$

John von Neumann (1903-1957)

## convex lipschitz functions

Let $\boldsymbol{X}=\left(\boldsymbol{X}_{1}, \ldots, \boldsymbol{X}_{\boldsymbol{n}}\right)$ have independent components taking values in $[0,1]$. Let $\boldsymbol{f}:[0,1]^{n} \rightarrow \mathbb{R}$ be quasi-convex such that $|f(x)-f(y)| \leq\|x-y\|$. Then

$$
\mathbb{P}\{f(X)>\mathbb{M} f(X)+t\} \leq 2 e^{-t^{2} / 4}
$$

and

$$
\mathbb{P}\{\boldsymbol{f}(\boldsymbol{X})<\mathbb{M} \boldsymbol{f}(\boldsymbol{X})-\boldsymbol{t}\} \leq 2 \boldsymbol{e}^{-\boldsymbol{t}^{2} / 4}
$$

Proof: Let $\boldsymbol{A}_{\boldsymbol{s}}=\{\boldsymbol{x}: \boldsymbol{f}(\boldsymbol{x}) \leq \boldsymbol{s}\} \subset[0,1]^{n}$. $\boldsymbol{A}_{\boldsymbol{s}}$ is convex. Since $\boldsymbol{f}$ is Lipschitz,

$$
f(x) \leq s+D\left(x, A_{s}\right) \leq s+d_{T}\left(x, A_{s}\right),
$$

By the convex distance inequality,

$$
\mathbb{P}\{\boldsymbol{f}(\boldsymbol{X}) \geq \boldsymbol{s}+\boldsymbol{t}\} \mathbb{P}\{\boldsymbol{f}(\boldsymbol{X}) \leq \boldsymbol{s}\} \leq \boldsymbol{e}^{-t^{2} / 4}
$$

Take $\boldsymbol{s}=\mathbb{M} \boldsymbol{f}(\boldsymbol{X})$ for the upper tail and $\boldsymbol{s}=\mathbb{M} \boldsymbol{f}(\boldsymbol{X})-\boldsymbol{t}$ for the lower tail.

## empirical processes

Let $\mathcal{T}$ be a countable index set.
For $\boldsymbol{i}=1, \ldots, \boldsymbol{n}$, let $\boldsymbol{X}_{\boldsymbol{i}}=\left(\boldsymbol{X}_{\boldsymbol{i}, \boldsymbol{s}}\right)_{\boldsymbol{s} \in \mathcal{T}}$ be vectors of real-valued random variables. Assume that $\boldsymbol{X}_{1}, \ldots, \boldsymbol{X}_{\boldsymbol{n}}$ are independent.
The empirical process is $\sum_{i=1}^{n} \boldsymbol{X}_{i, s}, \boldsymbol{s} \in \mathcal{T}$.
We study concentration of the supremum:

$$
\boldsymbol{Z}=\sup _{s \in \mathcal{T}} \sum_{i=1}^{n} \boldsymbol{X}_{\boldsymbol{i}, \boldsymbol{s}} .
$$

## empirical processes-the variance

We may use Efron-Stein: let

$$
Z_{i}=\sup _{s \in \mathcal{T}} \sum_{j: j \neq i} X_{j, s}
$$

and $\widehat{\boldsymbol{s}} \in \mathcal{T}$ be such that $\boldsymbol{Z}=\sum_{i=1}^{n} \boldsymbol{X}_{\boldsymbol{i}, \widehat{s}}$. Then

$$
\left(Z-Z_{i}\right)_{+} \leq\left(X_{i, \tilde{s}}\right)_{+} \leq \sup _{s \in \mathcal{T}}\left|\boldsymbol{X}_{i, s}\right|
$$

SO

$$
\operatorname{Var}(\boldsymbol{Z}) \leq \mathbb{E} \sum_{i=1}^{n}\left(\boldsymbol{Z}-\boldsymbol{Z}_{\boldsymbol{i}}\right)^{2} \leq \mathbb{E} \sum_{i=1}^{n} \sup _{s \in \mathcal{T}} \boldsymbol{X}_{\boldsymbol{i}, \boldsymbol{s}}^{2} .
$$

## empirical processes-the variance

A more clever use of Efron-Stein: suppose $\mathbb{E} \boldsymbol{X}_{i, s}=0$. Let $Z_{i}^{\prime}=\sup _{s \in \mathcal{T}}\left(\sum_{\boldsymbol{j} \neq i} \boldsymbol{X}_{\boldsymbol{j}, \boldsymbol{s}}+\boldsymbol{X}_{i, s}^{\prime}\right)$. Note that

$$
\left(\boldsymbol{z}-\boldsymbol{Z}_{\boldsymbol{i}}^{\prime}\right)_{+}^{2} \leq\left(\boldsymbol{X}_{i, \widehat{s}}-\boldsymbol{X}_{\boldsymbol{i}, \widehat{s}}^{\prime}\right)^{2}
$$

By Efron-Stein,

$$
\begin{aligned}
\operatorname{Var}(\boldsymbol{Z}) & \leq \mathbb{E} \sum_{i=1}^{n}\left(\boldsymbol{Z}-\boldsymbol{Z}_{\boldsymbol{i}}^{\prime}\right)_{+}^{2} \\
& \leq \mathbb{E} \sum_{i=1}^{n} \mathbb{E}^{\prime}\left[\left(\boldsymbol{X}_{\boldsymbol{i}, \widehat{s}}-\boldsymbol{X}_{\boldsymbol{i}, \widehat{s}}^{\prime}\right)^{2}\right] \\
& \leq \mathbb{E} \sum_{i=1}^{n}\left(\boldsymbol{X}_{i, \widehat{s}}^{2}+\mathbb{E}^{\prime}\left[\boldsymbol{X}_{i, \widehat{s}}^{\prime 2}\right]\right) \\
& \leq \mathbb{E} \sup _{s \in \mathcal{T}} \sum_{i=1}^{n} \boldsymbol{X}_{\boldsymbol{i}, \mathbf{s}}^{2}+\sup _{\boldsymbol{s} \in \mathcal{T}} \sum_{i=1}^{n} \mathbb{E} \boldsymbol{X}_{\boldsymbol{i}, \boldsymbol{s}}^{2} .
\end{aligned}
$$

## weak and strong variance

We have proved that

$$
\operatorname{Var}(\boldsymbol{Z}) \leq \boldsymbol{V} \quad \text { and } \quad \operatorname{Var}(\boldsymbol{Z}) \leq \Sigma^{2}+\sigma^{2}
$$

where

$$
\begin{gathered}
\boldsymbol{V}=\sum_{i=1}^{\boldsymbol{n}} \mathbb{E} \sup _{\boldsymbol{s} \in \mathcal{T}} \boldsymbol{X}_{\boldsymbol{i}, \boldsymbol{s}}^{2} \quad \text { strong variance } \\
\Sigma^{2}=\mathbb{E} \sup _{\boldsymbol{s} \in \mathcal{T}} \sum_{i=1}^{\boldsymbol{n}} \boldsymbol{X}_{\boldsymbol{i}, \boldsymbol{s}}^{2} \quad \text { weak variance } \\
\boldsymbol{\sigma}^{2}=\sup _{\boldsymbol{s} \in \mathcal{T}} \sum_{\boldsymbol{i}=1}^{\boldsymbol{n}} \mathbb{E} \boldsymbol{X}_{\boldsymbol{i}, \boldsymbol{s}}^{2} \quad \text { wimpy variance } \\
\boldsymbol{\sigma}^{2} \leq \Sigma^{2} \leq \boldsymbol{V}
\end{gathered}
$$

## weak and strong variance

If $\mathbb{E} \boldsymbol{X}_{i, s}=0$ and $\left|\boldsymbol{X}_{i, s}\right| \leq 1$, we also have, by symmetrization and contraction arguments,

$$
\Sigma^{2} \leq 8 \mathbb{E} \boldsymbol{Z}+\sigma^{2}
$$

and therefore

$$
\operatorname{Var}(\boldsymbol{Z}) \leq 8 \mathbb{E} \boldsymbol{Z}+2 \boldsymbol{\sigma}^{2}
$$

If the $\boldsymbol{X}_{\boldsymbol{i}}$ are also identicaly distributed, then

$$
\operatorname{Var}(\boldsymbol{Z}) \leq 2 \mathbb{E} \boldsymbol{Z}+\sigma^{2}
$$

## empirical processes-exponential inequalities

A Bernstein type inequality. "Talagrand's inequality".
Assume $\mathbb{E} \boldsymbol{X}_{i, s}=0$, and $\left|\boldsymbol{X}_{i, s}\right| \leq 1$. For $t \geq 0$,

$$
\mathbb{P}\{\boldsymbol{Z} \geq \mathbb{E} \boldsymbol{Z}+\boldsymbol{t}\} \leq \exp \left(-\frac{\boldsymbol{t}^{2}}{2\left(2\left(\Sigma^{2}+\boldsymbol{\sigma}^{2}\right)+\boldsymbol{t}\right)}\right)
$$

## proof.

For each $\boldsymbol{i}=1, \ldots, \boldsymbol{n}$, let $\boldsymbol{Z}_{i}^{\prime}=\sup _{\boldsymbol{s} \in \mathcal{T}}\left(\boldsymbol{X}_{\boldsymbol{i}, \boldsymbol{s}}^{\prime}+\sum_{\boldsymbol{j} \neq \boldsymbol{i}} \boldsymbol{X}_{\boldsymbol{j}, \boldsymbol{s}}\right)$.
We already proved that

$$
\sum_{i=1}^{n} \mathbb{E}^{\prime}\left(\boldsymbol{Z}-Z_{i}^{\prime}\right)_{+}^{2} \leq \sup _{\boldsymbol{s} \in \mathcal{T}} \sum_{i=1}^{n} X_{i, s}^{2}+\sigma^{2} \stackrel{\text { def. }}{=} W+\sigma^{2}
$$

By the exponential Efron-Stein inequality, for $\boldsymbol{\lambda} \in[0,1)$,

$$
\log \mathbb{E} e^{\lambda(Z-\mathbb{E} Z)} \leq \frac{\lambda}{1-\lambda} \log \mathbb{E} e^{\lambda\left(\boldsymbol{W}+\sigma^{2}\right)}
$$

$W$ is a self-bounding function, so

$$
\log \mathbb{E} \boldsymbol{e}^{\lambda W} \leq \Sigma^{2}\left(\boldsymbol{e}^{\lambda}-1\right)
$$

Putting things together implies the inequality.

## bousquet's inequality

A Bennett type inequality with the right constant.
Assume $\boldsymbol{X}_{1}, \ldots, \boldsymbol{X}_{\boldsymbol{n}}$ are i.i.d. with $\mathbb{E} \boldsymbol{X}_{\boldsymbol{i}, \boldsymbol{s}}=0$ and $\boldsymbol{X}_{\boldsymbol{i}, \boldsymbol{s}} \leq 1$.
For all $t \geq 0$,

$$
\mathbb{P}\{Z \geq \mathbb{E} Z+t\} \leq e^{-v h(t / v)}
$$

where $\boldsymbol{v}=2 \mathbb{E} \boldsymbol{Z}+\boldsymbol{\sigma}^{2}$ and $\boldsymbol{h}(\boldsymbol{u})=(1+\boldsymbol{u}) \log (1+\boldsymbol{u})-\boldsymbol{u}$. In particular,

$$
\mathbb{P}\{\boldsymbol{Z} \geq \mathbb{E} \boldsymbol{Z}+\boldsymbol{t}\} \leq \exp \left(-\frac{\boldsymbol{t}^{2}}{2(\boldsymbol{v}+\boldsymbol{t} / 3)}\right)
$$

## $\phi$ entropies

For a convex function $\phi$ on $[0, \infty)$, the $\phi$-entropy of $Z \geq 0$ is

$$
\boldsymbol{H}_{\phi}(Z)=\mathbb{E}[\phi(Z)]-\phi(\mathbb{E}[Z]) .
$$

$\boldsymbol{H}_{\phi}$ is subadditive:

$$
\boldsymbol{H}_{\phi}(Z) \leq \sum_{i=1}^{n} \mathbb{E}\left[\mathbb{E}\left[\phi(Z) \mid \boldsymbol{X}^{(i)}\right]-\phi\left(\mathbb{E}\left[Z \mid \boldsymbol{X}^{(i)}\right]\right)\right]
$$

if (and only if) $\phi$ is twice differentiable on ( $0, \infty$ ), and either $\phi$ is affine strictly positive and $1 / \phi^{\prime \prime}$ is concave.
$\phi(x)=x^{2}$ corresponds to Efron-Stein.
$x \log x$ is subadditivity of entropy.
We may consider $\phi(\boldsymbol{x})=\boldsymbol{x}^{\boldsymbol{p}}$ for $\boldsymbol{p} \in(1,2]$.

## generalized efron-stein

Define

$$
\begin{gathered}
Z_{i}^{\prime}=f\left(X_{1}, \ldots, X_{i-1}, X_{i}^{\prime}, X_{i+1}, \ldots, X_{n}\right), \\
V^{+}=\sum_{i=1}^{n}\left(Z-Z_{i}^{\prime}\right)_{+}^{2}
\end{gathered}
$$

For $\boldsymbol{q} \geq 2$ and $\boldsymbol{q} / 2 \leq \alpha \leq \boldsymbol{q}-1$,

$$
\begin{aligned}
& \mathbb{E}\left[(Z-\mathbb{E} \boldsymbol{Z})_{+}^{\boldsymbol{q}}\right] \\
& \quad \leq \mathbb{E}\left[(Z-\mathbb{E} \boldsymbol{Z})_{+}^{\alpha}\right]^{\boldsymbol{q} / \boldsymbol{\alpha}}+\alpha(\boldsymbol{q}-\alpha) \mathbb{E}\left[V^{+}(Z-\mathbb{E} \boldsymbol{Z})_{+}^{\boldsymbol{q - 2}}\right.
\end{aligned}
$$

and similarly for $\mathbb{E}\left[(Z-\mathbb{E} Z)_{-}^{q}\right]$.

## moment inequalities

We may solve the recursions, for $\boldsymbol{q} \geq 2$.
If $\boldsymbol{V}^{+} \leq \boldsymbol{c}$ for some constant $\boldsymbol{c} \geq 0$, then for all integers $\boldsymbol{q} \geq 2$,

$$
\left(\mathbb{E}\left[(Z-\mathbb{E} Z)_{+}^{\boldsymbol{q}}\right]\right)^{1 / \boldsymbol{q}} \leq \sqrt{\boldsymbol{K q c}},
$$

where $K=1 /(\boldsymbol{e}-\sqrt{\boldsymbol{e}})<0.935$.
More generally,

$$
\left(\mathbb{E}\left[(\boldsymbol{Z}-\mathbb{E} \boldsymbol{Z})_{+}^{\boldsymbol{q}}\right]\right)^{1 / \boldsymbol{q}} \leq 1.6 \sqrt{\boldsymbol{q}}\left(\mathbb{E}\left[\boldsymbol{V}^{+\boldsymbol{q} / 2}\right]\right)^{1 / \boldsymbol{q}}
$$

sums: khinchine's inequality

Let $\boldsymbol{X}_{1}, \ldots, \boldsymbol{X}_{\boldsymbol{n}}$ be independent Rademacher variables and $\boldsymbol{Z}=\sum_{i=1}^{n} a_{i} \boldsymbol{X}_{\boldsymbol{i}}$. For any integer $\boldsymbol{q} \geq 2$,

$$
\left(\mathbb{E}\left[\boldsymbol{Z}_{+}^{\boldsymbol{q}}\right]\right)^{1 / \boldsymbol{q}} \leq \sqrt{2 \boldsymbol{K} \boldsymbol{q}} \sqrt{\sum_{i=1}^{n} \boldsymbol{a}_{i}^{2}}
$$

Proof:

$$
\boldsymbol{V}^{+}=\sum_{i=1}^{n} \mathbb{E}\left[\left(\boldsymbol{a}_{i}\left(\boldsymbol{X}_{\boldsymbol{i}}-\boldsymbol{X}_{i}^{\prime}\right)\right)_{+}^{2} \mid X_{i}\right]=2 \sum_{i=1}^{n} a_{i}^{2} \mathbb{1}_{a_{i} X_{i}>0} \leq 2 \sum_{i=1}^{n} a_{i}^{2},
$$

Aleksandr Khinchin
(1894-1959)

## sums: rosenthal's inequality

Let $\boldsymbol{X}_{1}, \ldots, \boldsymbol{X}_{\boldsymbol{n}}$ be independent real-valued random variables with $\mathbb{E} \boldsymbol{X}_{\boldsymbol{i}}=0$. Define

$$
\boldsymbol{Z}=\sum_{\boldsymbol{i}=1}^{\boldsymbol{n}} \boldsymbol{X}_{\boldsymbol{i}}, \quad \boldsymbol{\sigma}^{2}=\sum_{\boldsymbol{i}=1}^{\boldsymbol{n}} \mathbb{E} \boldsymbol{X}_{\boldsymbol{i}}^{2}, \quad \boldsymbol{Y}=\max _{\boldsymbol{i}=1, \ldots, \boldsymbol{n}}\left|\boldsymbol{X}_{\boldsymbol{i}}\right|
$$

Then for any integer $\boldsymbol{q} \geq 2$,

$$
\left(\mathbb{E}\left[\boldsymbol{Z}_{+}^{\boldsymbol{q}}\right]\right)^{1 / \boldsymbol{q}} \leq \sigma \sqrt{10 \boldsymbol{q}}+3 \boldsymbol{q}\left(\mathbb{E}\left[\boldsymbol{Y}_{+}^{\boldsymbol{q}}\right]\right)^{1 / \boldsymbol{q}}
$$

## influences

If $\boldsymbol{A} \subset\{-1,1\}^{\boldsymbol{n}}$ and $\boldsymbol{X}=\left(\boldsymbol{X}_{1}, \ldots, \boldsymbol{X}_{\boldsymbol{n}}\right)$ is uniform, the influence of the $\boldsymbol{i}$-th variable is

$$
\boldsymbol{I}_{\boldsymbol{i}}(\boldsymbol{A})=\mathbb{P}\left\{\mathbb{1}_{\boldsymbol{X} \in A} \neq \mathbb{1}_{\boldsymbol{X}^{(i)} \in A}\right\}
$$

where $\boldsymbol{X}^{(i)}=\left(\boldsymbol{X}_{1}, \ldots, \boldsymbol{X}_{\boldsymbol{i}-1}, 1-\boldsymbol{X}_{\boldsymbol{i}}, \boldsymbol{X}_{\boldsymbol{i}+1}, \ldots, \boldsymbol{X}_{\boldsymbol{n}}\right)$.
The total influence is

$$
I(A)=\sum_{i=1}^{n} \boldsymbol{I}_{i}(A) .
$$

Note that

$$
I(A)=2^{-(n-1)}\left|\partial_{E}(A)\right|
$$

## influences: examples

dictatorship: $\boldsymbol{A}=\left\{\boldsymbol{x}: \boldsymbol{x}_{1}=1\right\} . \boldsymbol{I}(\boldsymbol{A})=1$.
parity: $\boldsymbol{A}=\left\{\boldsymbol{x}: \sum_{i} \mathbb{1}_{x_{i}=1}\right.$ is even $\} . \boldsymbol{I}(\boldsymbol{A})=\boldsymbol{n}$.
majority: $\boldsymbol{A}=\left\{x: \sum_{i} x_{i}>0\right\} . I(A) \approx \sqrt{2 n / \pi}$.
by Efron-Stein, $\quad \boldsymbol{P}(\boldsymbol{A})(1-\boldsymbol{P}(\boldsymbol{A})) \leq \frac{\boldsymbol{I}(\boldsymbol{A})}{4}$
so dictatorship has smallest total influence (if $\boldsymbol{P}(\boldsymbol{A})=1 / 2$ ).

## improved efron-stein on the hypercube

Recall that for any $\boldsymbol{f}:\{-1,1\}^{\boldsymbol{n}} \rightarrow \mathbb{R}$ under the uniform distribution,

$$
\operatorname{Ent}\left(\boldsymbol{f}^{2}\right) \leq 2 \mathcal{E}(\boldsymbol{f})
$$

where $\operatorname{Ent}\left(\boldsymbol{f}^{2}\right)=\boldsymbol{E}\left[\boldsymbol{f}^{2} \log \left(\boldsymbol{f}^{2}\right)\right]-\boldsymbol{E}\left[\boldsymbol{f}^{2}\right] \log \boldsymbol{E}\left[\boldsymbol{f}^{2}\right]$ and

$$
\mathcal{E}(\boldsymbol{f})=\frac{1}{4} \mathbb{E}\left[\sum_{i=1}^{n}\left(\boldsymbol{f}(\boldsymbol{X})-\boldsymbol{f}\left(\overline{\boldsymbol{X}}^{(i)}\right)\right)^{2}\right]
$$

This implies, for any non-negative $\boldsymbol{f}:\{-1,1\}^{n} \rightarrow[0, \infty)$,

$$
\boldsymbol{E}\left[\boldsymbol{f}^{2}\right] \log \frac{\boldsymbol{E}\left[\boldsymbol{f}^{2}\right]}{E[\boldsymbol{f}]^{2}} \leq 2 \mathcal{E}(\boldsymbol{f})
$$

improved efron-stein on the hypercube
Recall the Doob-martingale representation
$\boldsymbol{f}(\boldsymbol{X})-\boldsymbol{E f}=\sum_{i=1}^{n} \Delta_{i}$.
One easily sees that

$$
\mathcal{E}(\boldsymbol{f})=\sum_{i=1}^{n} \mathcal{E}\left(\Delta_{i}\right) .
$$

But then, by the previous lemma,

$$
\begin{aligned}
\mathcal{E}(\boldsymbol{f}) & \geq \sum_{j=1}^{n} \mathcal{E}\left(\left|\Delta_{j}\right|\right) \geq \frac{1}{2} \sum_{j=1}^{n} \boldsymbol{E}\left[\Delta_{j}^{2}\right] \log \frac{\boldsymbol{E}\left[\Delta_{j}^{2}\right]}{\left(\boldsymbol{E}\left|\Delta_{j}\right|\right)^{2}} \\
& =-\frac{1}{2} \operatorname{Var}(\boldsymbol{f}) \sum_{j=1}^{n} \frac{\boldsymbol{E}\left[\Delta_{j}^{2}\right]}{\operatorname{Var}(\boldsymbol{f})} \log \frac{\left(\boldsymbol{E}\left|\Delta_{j}\right|\right)^{2}}{\boldsymbol{E}\left[\Delta_{j}^{2}\right]} \\
& \geq-\frac{1}{2} \operatorname{Var}(\boldsymbol{f}) \log \frac{\sum_{j=1}^{n}\left(\boldsymbol{E}\left|\Delta_{j}\right|\right)^{2}}{\operatorname{Var}(\boldsymbol{f})}
\end{aligned}
$$

## improved efron-stein on the hypercube

We obtained that for any $\boldsymbol{f}:\{-1,1\}^{n} \rightarrow \mathbb{R}$,

$$
\operatorname{Var}(\boldsymbol{f}) \log \frac{\operatorname{Var}(\boldsymbol{f})}{\sum_{\boldsymbol{j}=1}^{n}\left(\boldsymbol{E}\left|\Delta_{j}\right|\right)^{2}} \leq 2 \mathcal{E}(\boldsymbol{f})
$$

(Falik and Samorodnitsky, 2007; Rossignol, 2006; Talagrand (1994)).
"Slightly" better than Efron-Stein.
Use this for $\boldsymbol{f}(\boldsymbol{x})=\mathbb{1}_{\boldsymbol{x} \in \boldsymbol{A}}$ for $\boldsymbol{A} \subset\{-1,1\}^{\boldsymbol{n}}$ :

$$
\boldsymbol{P}(\boldsymbol{A})(1-\boldsymbol{P}(\boldsymbol{A})) \log \frac{4 \boldsymbol{P}(\boldsymbol{A})(1-\boldsymbol{P}(\boldsymbol{A}))}{\sum_{i} \boldsymbol{I}_{\boldsymbol{i}}(\boldsymbol{A})^{2}} \leq \frac{\boldsymbol{I}(\boldsymbol{A})}{4}
$$

## kahn, kalai, linial

Corollary: (Kahn, Kalai, Linial, 1988).

$$
\max _{i} \boldsymbol{I}_{i}(\boldsymbol{A}) \geq \frac{\boldsymbol{P}(\boldsymbol{A})(1-\boldsymbol{P}(\boldsymbol{A})) \log \boldsymbol{n}}{\boldsymbol{n}}
$$

If the influences are equal,

$$
\boldsymbol{I}(\boldsymbol{A}) \geq \boldsymbol{P}(\boldsymbol{A})(1-\boldsymbol{P}(\boldsymbol{A})) \log \boldsymbol{n}
$$

Another corollary: (Friedgut, 1998).
If $\boldsymbol{I}(\boldsymbol{A}) \leq \boldsymbol{c}, \boldsymbol{A}$ (basically) depends on a bounded number of variables. $\boldsymbol{A}$ is a "junta."

## threshold phenomena

Let $\boldsymbol{A} \subset\{-1,1\}^{\boldsymbol{n}}$ be a monotone set and let $\boldsymbol{X}=\left(\boldsymbol{X}_{1}, \ldots, \boldsymbol{X}_{\boldsymbol{n}}\right)$ be such that

$$
\begin{gathered}
\mathbb{P}\left\{\boldsymbol{X}_{\boldsymbol{i}}=1\right\}=\boldsymbol{p} \quad \mathbb{P}\left\{\boldsymbol{X}_{\boldsymbol{i}}=-1\right\}=1-\boldsymbol{p} \\
\boldsymbol{P}_{\boldsymbol{p}}(\boldsymbol{A})=\sum_{x \in \boldsymbol{A}} \boldsymbol{p}^{\|x\|}(1-\boldsymbol{p})^{\boldsymbol{n}-\|x\|}
\end{gathered}
$$

is an increasing function of $\boldsymbol{p} \in[0,1]$.
Let $\boldsymbol{p}_{\boldsymbol{a}}$ be such that $\boldsymbol{P}_{\boldsymbol{p}_{\boldsymbol{a}}}(\boldsymbol{A})=\boldsymbol{a}$.
Critical value $=\boldsymbol{p}_{1 / 2}$
Threshold width: $\boldsymbol{p}_{1-\varepsilon}-\boldsymbol{p}_{\boldsymbol{\varepsilon}}$

## two (extreme) examples

threshold width $=1-2 \varepsilon$
majority (with $\boldsymbol{n}=101$ )

$$
\leq \sqrt{\log (1 / \varepsilon) /(2 \boldsymbol{n})}
$$

In what cases do we have a quick transition?

## russo's lemma

If $\boldsymbol{A}$ is monotone,

$$
\frac{d P_{p}(A)}{d p}=I^{(p)}(A)
$$

The Kahn, Kalai, Linial result, generalized for $\boldsymbol{p} \neq 1 / 2$, implies that
if $\boldsymbol{A}$ is such that $\boldsymbol{I}_{1}^{(p)}=\boldsymbol{I}_{2}^{(p)}=\cdots=\boldsymbol{I}_{n}^{(p)}$, then

$$
\boldsymbol{p}_{1-\varepsilon}-\boldsymbol{p}_{\varepsilon}=\boldsymbol{O}\left(\frac{\log \frac{1}{\varepsilon}}{\log \boldsymbol{n}}\right)
$$

On the other hand, if $\boldsymbol{p}_{3 / 4}-\boldsymbol{p}_{1 / 4} \geq \boldsymbol{c}$ then $\boldsymbol{A}$ is (basically) a junta.
